June 11, 2023 at 13:14
1* **Introduction.** This file contains code common to CTANGLE, CWEAVE, and CTWILL, which roughly concerns the following problems: character uniformity, input routines, error handling and parsing of command line. We have tried to concentrate in this file all the system dependencies, so as to maximize portability.

In the texts below we will sometimes use CWEB to refer to any of the three component programs, if no confusion can arise.

The file begins with a few basic definitions.

(Include files 3*)
(Preprocessor definitions)
(Common code for CWEAVE and CTANGLE 2*)
(Global variables 18*)
(Predelclaration of procedures 7*)

2* The details will be filled in due course. The interface "common.h" of this COMMON module is included first. It is also used by the main programs.

First comes general stuff:

(Common code for CWEAVE and CTANGLE 2*)≡

typedef uint8_t eight_bits;
typedef uint16_t sixteen_bits;
typedef enum {
  ctangle, cweave, ctwill
} cweb;
extern cweb program; ▶ CTANGLE or CWEB or CTWILL? ◀
extern int phase; ▶ which phase are we in? ◀

See also sections 4*, 5*, 6*, 8*, 9*, 11*, 13*, and 14*.
This code is used in section 1*.

3* You may have noticed that almost all "strings" in the CWEB sources are placed in the context of the `.` macro. This is just a shortcut for the `gettext` function from the “GNU gettext utilities.” For systems that do not have this library installed, we wrap things for neutral behavior without internationalization. For backward compatibility with pre-ANSI compilers, we replace the “standard” header file `stdbool.h` with the KPATHSEA interface `simpletypes.h`.

```
#define _(s) gettext(s)
```

(Include files 3*)≡

#include `<ctype.h>` ▶ definition of isalpha, isdigit and so on ◀
#include `<kpathsea/simpletypes.h>` ▶ boolean, true and false ◀
#include `<stddef.h>` ▶ definition of ptdiff_t ◀
#include `<stdint.h>` ▶ definition of uint8_t and uint16_t ◀
#include `<stdio.h>` ▶ definition of printf and friends ◀
#include `<stdlib.h>` ▶ definition of getenv and exit ◀
#include `<string.h>` ▶ definition of strlen, strcmp and so on ◀

ifndef HAVE_GETTEXT
#define HAVE_GETTEXT 0
endif

#if HAVE_GETTEXT
#include `<libintl.h>`
#else
#define gettext(a) a
#endif

See also sections 91*, 93*, and 96*.
This code is used in section 1*. 
4* Code related to the character set:

```c
#define and_and  °4  ▷ '&&'; corresponds to MIT's ∧ ∧
#define lt_lt  °20  ▷ '<<''; corresponds to MIT's < <
#define gt_gt  °21  ▷ '>>'; corresponds to MIT's ⊻ ⊻
#define plus_plus  °13  ▷ '++'; corresponds to MIT's ⊕ ⊕
#define minus_minus  °1  ▷ '--'; corresponds to MIT's ◊ ◊
#define minus_gt  °31  ▷ '--'; corresponds to MIT's ↓ ↓
#define non_eq  °32  ▷ '!='; corresponds to MIT's ≠ ≠
#define lt_eq  °34  ▷ '<='; corresponds to MIT's ≤ ≤
#define gt_eq  °35  ▷ '>='; corresponds to MIT's ≥ ≥
#define eq_eq  °36  ▷ '=='; corresponds to MIT's ≡ ≡
#define or_or  °37  ▷ '||'; corresponds to MIT's ∨ ∨
#define dot_dot_dot  °16  ▷ '...'; corresponds to MIT's ⋯ ⋯
#define colon_colon  °6  ▷ '::'; corresponds to MIT's ∈ ∈
#define period_ast  °26  ▷ '.'; corresponds to MIT's ⊙ ⊙
#define minus_gt_ast  °27  ▷ '-*'; corresponds to MIT's ⊲ ⊲
#define compress(c) if (loc++ ≤ limit) return c
```

(Common code for CWEAVE and CTANGLE 2*) ++=

```c
extern char section_text[];  ▷ text being sought for ∧
extern char *section_text_end;  ▷ end of section_text ∧
extern char *id_first;  ▷ where the current identifier begins in the buffer ∧
extern char *id_loc;  ▷ just after the current identifier in the buffer ∧
```

5* Code related to input routines:

```c
#define isalpha(c) (isalpha((int)(c)) ∧ ((eight_bits)(c) < °200))
#define isdigit(c) (isdigit((int)(c)) ∧ ((eight_bits)(c) < °200))
#define isspace(c) (isspace((int)(c)) ∧ ((eight_bits)(c) < °200))
#define islower(c) (islower((int)(c)) ∧ ((eight_bits)(c) < °200))
#define isupper(c) (isupper((int)(c)) ∧ ((eight_bits)(c) < °200))
#defineisdigit(c) (isdigit((int)(c)) ∧ ((eight_bits)(c) < °200))
#define isalpha(c) ((c) ≡ 'a' ∨ (c) ≡ 'z')  ▷ non-alpha characters allowed in identifier ∧
#define ishigh(c) ((eight_bits)(c) ≥ °177)
```

(Common code for CWEAVE and CTANGLE 2*) ++=

```c
extern char buffer[];  ▷ where each line of input goes ∧
extern char *buffer_end;  ▷ end of buffer ∧
extern char *loc;  ▷ points to the next character to be read from the buffer ∧
extern char *limit;  ▷ points to the last character in the buffer ∧
```
6* Code related to file handling:

`format line x`  ▷ `make line an unreserved word` ◄

```c
#include <stdio.h>

#define max_file_name_length 1024
#define cur_file file[include_depth]  ▷ `current file` ◄
#define cur_file_name file_name[include_depth]  ▷ `current file name` ◄
#define cur_line line[include_depth]  ▷ `number of current line in current file` ◄
#define web_file file[0]  ▷ `main source file` ◄
#define web_file_name file_name[0]  ▷ `main source file name` ◄

extern int include_depth;  ▷ `current level of nesting` ◄
extern FILE *file[];  ▷ `stack of non-change files` ◄
extern FILE *change_file;  ▷ `change file` ◄
extern char file_name[] [max_file_name_length];  ▷ `stack of non-change file names` ◄
extern char change_file_name[];  ▷ `name of change file` ◄
extern char check_file_name[];  ▷ `name of check file` ◄
extern int line[];  ▷ `number of current line in the stacked files` ◄
extern int change_line;  ▷ `number of current line in change file` ◄
extern int change_depth;  ▷ `where @y originated during a change` ◄
extern boolean input_has Ended;  ▷ `if there is no more input` ◄
extern boolean changing;  ▷ `if the current line is from change_file` ◄
extern boolean web_file_open;  ▷ `if the web file is being read` ◄
```

7* (Predeclaration of procedures 7*) ≡

```c
extern boolean get_line(void);  ▷ `inputs the next line` ◄
extern void check_complete(void);  ▷ `checks that all changes were picked up` ◄
extern void reset_input(void);  ▷ `initialize to read the web file and change file` ◄
```

See also sections 10*, 12*, 15*, 24, 28, 33, 55, 64, 76, and 98*.

This code is used in section 1*.

8* Code related to section numbers:

```c
extern sixteen_bits section_count;  ▷ `the current section number` ◄
extern boolean changed_section[];  ▷ `is the section changed?` ◄
extern boolean change_pending;  ▷ `is a decision about change still unclear?` ◄
extern boolean print_where;  ▷ `tells CTANGLE to print line and file info` ◄
```
9*  Code related to identifier and section name storage:

```c
#ifndef length
#define length(c) ((c + 1) - (char *)byte_start - (c) - byte_start)  /* the length of a name */
#endif

#ifndef print_id
#define print_id(c) term_write((char *)byte_start, length(c))  /* print identifier */
#endif

#ifndef rlink
#define rlink dummy.Rlink  /* right link in binary search tree for section names */
#endif

#ifndef root
#define root name_dir->rlink  /* the root of the binary search tree for section names */
#endif

<Common code for CWEAVE and CTANGLE 2*> ±≡

typedef struct name_info {
    char *byte_start;  /* beginning of the name in byte_mem */
    struct name_info *link;
    union {
        struct name_info *Rlink;  /* right link in binary search tree for section names */
        char Ilk;  /* used by identifiers in CWEAVE only */
    } dummy;
    void *equiv_or_xref;  /* info corresponding to names */
} name_info;  /* contains information about an identifier or section name */
typedef name_info *name_pointer;  /* pointer into array of name_infos */
typedef name_pointer *hash_pointer;

extern char byte_mem[];  /* characters of names */
extern char *byte_mem_end;  /* end of byte_mem */
extern char *byte_ptr;  /* first unused position in byte_mem */
extern name_info name_dir[];  /* information about names */
extern name_pointer name_dir_end;  /* end of name_dir */
extern name_pointer name_ptr;  /* first unused position in name_dir */
extern name_pointer hash[];  /* heads of hash lists */
extern hash_pointer hash_end;  /* end of hash */
extern hash_pointer h;  /* index into hash-head array */

<Predeclaration of procedures 7*> ±≡

external boolean names_match(name_pointer, const char *, size_t, eight_bits);
external name_pointer id_lookup(const char *, const char *, eight_bits);
    /* looks up a string in the identifier table */
external name_pointer section_lookup(char *, char *, boolean);  /* finds section name */
external void init_node(name_pointer);
external void init_p(name_pointer, eight_bits);
external void print_prefix_name(name_pointer);
external void print_section_name(name_pointer);
external void print_section_name(char *, name_pointer);
```

10*  <Common code for CWEAVE and CTANGLE 2*> ±≡

11*  Code related to error handling:

```c
#define spotless 0  /* history value for normal jobs */
#define harmless_message 1  /* history value when non-serious info was printed */
#define error_message 2  /* history value when an error was noted */
#define fatal_message 3  /* history value when we had to stop prematurely */
#define mark_harmless if (history ≡ spotless) history ← harmless_message
#define mark_error history ← error_message
#define confusion(s) fatal("!\u201cThis\u201d can\'t happen!\", s)
```

<Common code for CWEAVE and CTANGLE 2*> ±≡

```c
extern int history;  /* indicates how bad this run was */
```
§12  (Predeclaration of procedures \(7^*\)) +≡

- `extern int wrap_up(void);`  \(\triangleright\) indicate history and exit \(<\)
- `extern void err_print(const char *);`  \(\triangleright\) print error message and context \(<\)
- `extern void fatal(const char *, const char *);`  \(\triangleright\) issue error message and die \(<\)
- `extern void overflow(const char *);`  \(\triangleright\) succumb because a table has overflowed \(<\)

13.*  Code related to command line arguments:

```c
#define show_banner flags[\'b\']   \(\triangleright\) should the banner line be printed? \(<\)
#define show_progress flags[\'p\']   \(\triangleright\) should progress reports be printed? \(<\)
#define show_happiness flags[\'h\']   \(\triangleright\) should lack of errors be announced? \(<\)
#define show_stats flags[\'s\']   \(\triangleright\) should statistics be printed at end of run? \(<\)
#define make_xrefs flags[\'x\']   \(\triangleright\) should cross references be output? \(<\)
#define check_for_change flags[\'c\']   \(\triangleright\) check temporary output for changes \(<\)
```

(Common code for \texttt{CWEB} and \texttt{CTANGLE} \(2^*\)) +≡

- `extern int argc;`  \(\triangleright\) copy of \texttt{ac} parameter to \texttt{main} \(<\)
- `extern char **argv;`  \(\triangleright\) copy of \texttt{av} parameter to \texttt{main} \(<\)
- `extern char C_file_name[];`  \(\triangleright\) name of \texttt{C} file \(<\)
- `extern char tex_file_name[];`  \(\triangleright\) name of \texttt{tex} file \(<\)
- `extern char idx_file_name[];`  \(\triangleright\) name of \texttt{idx} file \(<\)
- `extern char scn_file_name[];`  \(\triangleright\) name of \texttt{scn} file \(<\)
- `extern boolean flags[];`  \(\triangleright\) an option for each 7-bit code \(<\)
- `extern const char *use_language;`  \(\triangleright\) prefix to \texttt{cwebmac.tex} in \TeX\ output \(<\)

14.*  Code related to output:

```c
#define update_terminal fflush(stdout)   \(\triangleright\) empty the terminal output buffer \(<\)
#define new_line putchar(\'\n\')
```

(\textit{Common code for \texttt{CWEB} and \texttt{CTANGLE} \(2^*\)}) +≡

- `extern FILE *C_file;`  \(\triangleright\) where output of \texttt{CTANGLE} goes \(<\)
- `extern FILE *tex_file;`  \(\triangleright\) where output of \texttt{CWEB} goes \(<\)
- `extern FILE *idx_file;`  \(\triangleright\) where index from \texttt{CWEB} goes \(<\)
- `extern FILE *scn_file;`  \(\triangleright\) where list of sections from \texttt{CWEB} goes \(<\)
- `extern FILE *active_file;`  \(\triangleright\) currently active file for \texttt{CWEB} output \(<\)
- `extern FILE *check_file;`  \(\triangleright\) temporary output file \(<\)

15.*  The procedure that gets everything rolling:

(\textit{Predeclaration of procedures \(7^*\)}) +≡

```c
void common_init(void);
void print_stats(void);
void cb_show_banner(void);
```

16.*  The following parameters are sufficient to handle \TeX\ (converted to \texttt{CWEB}), so they should be sufficient for most applications of \texttt{CWEB}.

```c
#define buf_size 1000  \(\triangleright\) maximum length of input line, plus one \(<\)
#define longest_name 10000
  \(\triangleright\) file names, section names, and section texts shouldn’t be longer than this \(<\)
#define long_buf_size (buf_size + longest_name)  \(\triangleright\) for \texttt{CWEB} \(<\)
#define max_bytes 1000000
  \(\triangleright\) the number of bytes in identifiers, index entries, and section names; must be less than \(2^{24}\) \(<\)
#define max_names 10239  \(\triangleright\) number of identifiers, strings, section names; must be less than 10240 \(<\)
#define max_sections 4000  \(\triangleright\) greater than the total number of sections \(<\)
```
17*  End of COMMON interface.

18*  In certain cases CTANGLE and CWEAVE should do almost, but not quite, the same thing. In these cases we’ve written common code for both, differentiating between the two by means of the global variable program. And CTWILL adds some extra twists.

(\texttt{Global variables}) \equiv \texttt{cweb \ program}; \quad \triangledown \text{CTANGLE or CWEAVE or CTWILL?} \ < \\
See also sections 19, 21, 22, 25*, 26, 37, 43, 44, 46*, 65, 73*, 83*, 86*, and 87*.

This code is used in section 1*.

20*  There’s an initialization procedure that gets both CTANGLE and CWEAVE off to a good start. We will fill in the details of this procedure later.

\begin{verbatim}
void common_init(void)
{
  \langle Initialize pointers 45 \rangle
  \langle Set up PROGNAME feature and initialize the search path mechanism 94* \rangle
  \langle Set locale and bind language catalogs 92* \rangle
  \langle Set the default options common to CTANGLE and CWEAVE 74* \rangle
  \langle Scan arguments and open output files 84* \rangle
}
\end{verbatim}

23*  In the unlikely event that your standard I/O library does not support feof, getc, and ungetc you may have to change things here.

\begin{verbatim}
static boolean input_line(FILE *fp) \triangledown \text{copies a line into buffer or returns false} <
{
  int c ← EOF; \triangledown \text{character read; initialized so some compilers won’t complain} <
  char *k; \triangledown \text{where next character goes} <
  if (feof(fp)) return false; \triangledown \text{we have hit end-of-file} <
  limit ← k ← buffer; \triangledown \text{beginning of buffer} <
  while (k ≤ buffer.end ∧ (c ← getc(fp)) ≠ EOF ∧ c ≠ ‘\n’) \langle
    if ((*++k) ← c) ≠ ‘\n’ ∧ c ≠ ‘\r’) limit ← k;
  \rangle
  if (k > buffer.end)
    if ((c ← getc(fp)) ≠ EOF ∧ c ≠ ‘\n’) {
      ungetc(c, fp); loc ← buffer; err_print(\text{"Input line too long"});
    }
  if (c ≡ EOF ∧ limit ≡ buffer) return false; \triangledown \text{there was nothing after the last newline} <
  return true;
}
\end{verbatim}
Now comes the problem of deciding which file to read from next. Recall that the actual text that \texttt{CWEB} should process comes from two streams: a \texttt{web.file}, which can contain possibly nested include commands \texttt{@i}, and a \texttt{change.file}, which might also contain includes. The \texttt{web.file} together with the currently open include files form a stack \texttt{file}, whose names are stored in a parallel stack \texttt{file.name}. The boolean \texttt{changing} tells whether or not we’re reading from the \texttt{change.file}.

The line number of each open file is also kept for error reporting and for the benefit of \texttt{CTANGLE}.

\begin{verbatim}
⟨Global variables⟩ *= int include_depth;   ▷ current level of nesting ◀
FILE *file[max_include_depth]; ▷ stack of non-change files ◀
FILE *change_file;      ▷ change file ◀
char file_name[max_include_depth][max_file_name_length]; ▷ stack of non-change file names ◀
char change_file_name[max_file_name_length]; ▷ name of change file ◀
int line[max_include_depth]; ▷ number of current line in the stacked files ◀
int change_line;   ▷ number of current line in change file ◀
int change_depth; ▷ where @y originated during a change ◀
boolean input_has Ended; ▷ if there is no more input ◀
boolean changing; ▷ if the current line is from \texttt{change_file} ◀
boolean web_file_open ← false; ▷ if the \texttt{web_file} is being read ◀
\end{verbatim}

\begin{enumerate}
\item While looking for a line that begins with \texttt{@x} in the change file, we allow lines that begin with \texttt{@}, as long as they don’t begin with \texttt{@y}, \texttt{@z}, or \texttt{@i} (which would probably mean that the change file is fouled up).
\item \begin{verbatim}
while (true) {
    change_line ++;
    if (!input Ln(change_file)) return;
    if (limit < buffer + 2) continue;
    if (buffer[0] ≠ 'a') continue;
    if ((xisupper(buffer[1])) buffer[1] ← tolower((int) buffer[1]);
    if (buffer[1] ≡ 'x') break;
        loc ← buffer + 2; err.print(("!\_Missing_\@x_in_\change_\file");
    }
}
\end{verbatim}
\end{enumerate}

This code is used in section 27.

\begin{enumerate}
\item Here we are looking at lines following the \texttt{@x}.
\item \begin{verbatim}
do {
    change_line ++;
    if (!input Ln(change_file)) {
        err.print(("!\_Change_\file_ended_after_\@x"); return;
    }
} while (limit ≡ buffer);
\end{verbatim}
\end{enumerate}

This code is used in section 27.
The following procedure is used to see if the next change entry should go into effect; it is called only
when \textit{changing} is \textit{false}. The idea is to test whether or not the current contents of \textit{buffer} matches the current
contents of \textit{change_buffer}. If not, there’s nothing more to do; but if so, a change is called for: All of the
text down to the \texttt{@y} is supposed to match. An error message is issued if any discrepancy is found. Then the
procedure prepares to read the next line from \textit{change_file}.

When a match is found, the current section is marked as changed unless the first line after the \texttt{@x}
and after the \texttt{@y} both start with either ‘@*’ or ‘@␣’ (possibly preceded by whitespace).

This procedure is called only when \textit{buffer} < \textit{limit}, i.e., when the current line is nonempty.

\begin{verbatim}
#define if_section_start_make_pending(b)
   *limit ← '!'; for (loc ← buffer; xisspace(*loc); loc ++); *limit ← '␣';
   if (*loc ≡ '@' ∧ (xisspace(*loc + 1)) ∨ *(loc + 1) ≡ '*') change_pending ← b

static void check_change(void)  // switches to change_file if the buffers match
{
   int n ← 0;  // the number of discrepancies found
   if (lines_dont_match) return;
   change_pending ← false;
   if (!changed_section[section_count]) {
      if_section_start_make_pending(true);
      if (!change_pending) changed_section[section_count] ← true;
   }
   while (true) {
      changing ← print_where ← true; change_line ++;
      if (!inputLn(change_file)) {
         err_print("@yChange_file ended before @y"); change_limit ← change_buffer;
         changing ← false; return;
      }
      if (limit > buffer + 1 ∧ buffer[0] ≡ '@') {
         char xyz_code ← xisupper(buffer[1]) ? tolower((int)buffer[1]) : buffer[1];
         ⟨If the current line starts with @y, report any discrepancies and return 34⟩
      }
      ⟨Move buffer and limit to change_buffer and change_limit 31⟩
      changing ← false; cur_line ++;
      while (!inputLn(cur_file)) {  // pop the stack or quit
         if (include_depth ≡ 0) {
            err_print("!CWEB_file ended during a change"); input_has Ended ← true; return;
         }
         include_depth ←; cur_line ++;
      }
      if (lines_dont_match) n ++;
   }
}
\end{verbatim}
34* (If the current line starts with $@y$, report any discrepancies and return 34*)

$$\begin{align*}
\text{if} \ (xyz\_code \equiv \ 'x' \lor xyz\_code \equiv \ 'z') \ {\{}
&\quad \text{loc} \leftarrow \text{buffer} + 2; \ \text{err\_print}(\_!Where\_is\_the\_matching@y?)\}; \\
\text{else if} \ (xyz\_code \equiv \ 'y') \ {\{}
&\quad \text{if} \ (n > 0) \ {\{}
&\qquad \text{loc} \leftarrow \text{buffer} + 2; \ \text{printf}(\_!\text{Hmm}...%d, \ n); \\
&\qquad \text{err\_print}(\_of\_the\_preceding\_lines\_failed\_to\_match)\}; \\
&\qquad \text{change\_depth} \leftarrow \text{include\_depth}; \ \text{return}; \\
\}}
\end{align*}$$

This code is used in section 32*.

36* The following code opens the input files.

$$\begin{align*}
\text{Open input files 36*} \equiv \\
\text{if} \ ((\text{found\_filename} \leftarrow \text{kpse\_find\_cweb(web\_file\_name})) \equiv \Lambda \\
\quad \lor (\text{web\_file} \leftarrow \text{fopen(\text{found\_filename}, "r"))} \equiv \Lambda)
&\quad \text{fatal}(\_\text{Cannot\_open\_input\_file}, \text{web\_file\_name}); \\
\text{else if} \ (\text{strlen(\text{found\_filename})} < \text{max\_file\_name\_length}) \ {\{}
&\quad \text{\▷ Copy name for #line directives. \}<}
&\quad \text{if} \ (\text{strncmp(\text{found\_filename}, ".\", 2) \equiv 0) ? 2 : 0}); \\
&\quad \text{\▷ Copy name for #line directives. \}<}
&\quad \text{\free{\text{found\_filename}}}; \\
\}}
\end{align*}$$

This code is used in section 35.
38* boolean get_line(void) ▷ inputs the next line ◁
{
    restart:
    if (changing ∧ include_depth ≡ change_depth)
        { Read from change_file and maybe turn off changing 41* }
    if (¬changing ∨ include_depth > change_depth) {
        { Read from cur_file and maybe turn on changing 40 }
        if (changing ∧ include_depth ≡ change_depth) goto restart;
    }
    if (input_has_ended) return false;
    loc ← buffer; *limit ← ‘\’;
    if (buffer[0] ≡ ‘@’ ∧ (buffer[1] ≡ ’i’ ∨ buffer[1] ≡ ’I’)) {
        loc ← buffer + 2; *limit ← ‘\’;
        while (*loc ≡ ‘\’ ∨ *loc ≡ ’\t’) loc++;
        if (loc ≥ limit) {
            err_print("\Include_file\name\not\given"); goto restart;
        }
    }
    if (include_depth ≥ max_include_depth − 1) {
        err_print("\Too\many\nested\includes"); goto restart;
    }
    include_depth++; ▷ push input stack ◁
    { Try to open include file, abort push if unsuccessful, go to restart 39* }
}
return true;
39* When an \@i line is found in the \texttt{cur_file}, we must temporarily stop reading it and start reading from the named include file. The \@i line should give a complete file name with or without double quotes. The actual file lookup is done with the help of the KPATHSEA library; see section \langle File lookup with KPATHSEA 93 \rangle for details. The remainder of the \@i line after the file name is ignored.

\text{prime\_the\_change\_buffer}(); \text{changing} & \leftarrow \neg \text{changing}; \text{print\_where} & \leftarrow \text{true};
\}
\}
\}
\}
\]

This code is used in section 38*.

42* At the end of the program, we will tell the user if the change file had a line that didn’t match any relevant line in web_file.

\begin{verbatim}
void check_complete(void)
{
    if (change_limit \neq change_buffer) \triangleright \text{changing is false} \triangleleft \\
    \text{strncpy}(\text{buffer}, \text{change_buffer}, \text{(size\_t)}(\text{change_limit} - \text{change_buffer} + 1));
    \text{limit} & \leftarrow \text{buffer} + (\text{ptrdiff\_t})(\text{change_limit} - \text{change_buffer}); \text{changing} & \leftarrow \text{true};
    \text{change\_depth} & \leftarrow \text{include\_depth}; \text{loc} & \leftarrow \text{buffer};
    \text{err_print}(\text{"!\_\text{Change\_file\_entry\_did\_not\_match\"});}
}
\end{verbatim}

46* The hash table itself consists of hash_size entries of type \text{name\_pointer}, and is updated by the id_lookup procedure, which finds a given identifier and returns the appropriate \text{name\_pointer}. The matching is done by the function \text{names\_match}, which is slightly different in CWEAVE and CTANGLE. If there is no match for the identifier, it is inserted into the table.

\begin{verbatim}
#define hash_size 8501 \triangleright \text{should be prime} \triangleleft
\begin{align*}
\text{Global variables} & \ 18* \ + \equiv \\
\text{name\_pointer} & \text{hash[hash\_size]}; \quad \triangleright \text{heads of hash lists} \triangleleft \\
\text{hash\_pointer} & \text{hash\_end} & \leftarrow \text{hash} + \text{hash\_size} - 1; \quad \triangleright \text{end of hash} \triangleleft \\
\text{hash\_pointer} & \text{h}; \quad \triangleright \text{index into hash-head array} \triangleleft
\end{align*}
\end{verbatim}
The information associated with a new identifier must be initialized in a slightly different way in \texttt{CWEAVE} than in \texttt{CTANGLE}; hence the \texttt{init\_p} procedure.

\begin{verbatim}
(Enter a new name into the table at position \( p \)) \equiv

\begin{verbatim}
if (byte\_ptr + l > byte\_mem\_end) overflow(_."byte\_memory")
if (name\_ptr \geq name\_dir\_end) overflow(_."name")
strncpy(byte\_ptr, first, l); (++name\_ptr)-byte\_start \leftarrow byte\_ptr += l; init\_p(p, t);
\end{verbatim}

This code is used in section 48.

Adding a section name to the tree is straightforward if we know its parent and whether it’s the \textit{rlink} or \textit{llink} of the parent. As a special case, when the name is the first section being added, we set the “parent” to \( \Lambda \). When a section name is created, it has only one chunk, which however may be just a prefix; the full name will hopefully be unveiled later. Obviously, \textit{prefix\_length} starts out as the length of the first chunk, though it may decrease later.

The information associated with a new node must be initialized differently in \texttt{CWEAVE} and \texttt{CTANGLE}; hence the \texttt{init\_node} procedure, which is defined differently in \texttt{cweave.w} and \texttt{ctangle.w}.

\begin{verbatim}
static name\_pointer add\_section\_name(  
    name\_pointer par,  
    int c,  
    char *first,  
    char *last,  
    boolean ispref)  
{
    name\_pointer p \leftarrow name\_ptr;  
    char *s \leftarrow first\_chunk(p);
    size\_t name\_len \leftarrow (size\_t)(last - first + (int) ispref);  
    if (s + name\_len > byte\_mem\_end) overflow(_."byte\_memory")
    if (name\_ptr + 1 \geq name\_dir\_end) overflow(_."name")
    (++name\_ptr)-byte\_start \leftarrow byte\_ptr \leftarrow s + name\_len;
    if (ispref) {
        *(byte\_ptr - 1) \leftarrow ' '; name\_len--; name\_ptr\_link \leftarrow name\_dir;
        (++name\_ptr)-byte\_start \leftarrow byte\_ptr;
    }
    set\_prefix\_length(p, name\_len); strncpy(s, first, name\_len); p\_llink \leftarrow p\_rlink \leftarrow \Lambda; init\_node(p);
    return par \equiv \Lambda ? (root \leftarrow p) : c \equiv less ? (par\_llink \leftarrow p) : (par\_rlink \leftarrow p);
} 
\end{verbatim}
58* static void extend_section_name(name_pointer p, ▷ name to be extended ◁
  char *first, ▷ beginning of extension text ◁
  char *last, ▷ one beyond end of extension text ◁
  boolean ispref) ▷ are we adding a prefix or a full name? ◁
{
  char *s;
  name_pointer q ← p + 1;
  size_t name_len ← (size_t)(last − first + (int) ispref);
  if (name_ptr ≥ name_dir_end) overflow(_"name");
  while (q-link ≠ name_dir) q ← q-link;
  q-link ← name_ptr; s ← name_ptr-byte_start; name_ptr-link ← name_dir;
  if (s + name_len > byte_mem_end) overflow(_"byte_memory");
  (name_ptr-byte_start ← byte_ptr ← s + name_len; strncpy(s, first, name_len);
  if (ispref) *(byte_ptr − 1) ← ' ';

60* A legal new name matches an existing section name if and only if it matches the shortest prefix of that section name. Therefore we can limit our search for matches to shortest prefixes, which eliminates the need for chunk-chasing at this stage.

<Look for matches for new name among shortest prefixes, complaining if more than one is found 60*> ≡
while (p) { ▷ compare shortest prefix of p with new name ◁
  c ← web_strcmp(first, name_len, first_chunk(p), prefix_length(p));
  if (c ≡ less ∨ c ≡ greater) { ▷ new name does not match p ◁
    if (r ≡ Λ) ▷ no previous matches have been found ◁
      par ← p;
      p ← (c ≡ less ? p-link : p-link);
  } else { ▷ new name matches p ◁
    if (r ≡ Λ) { ▷ and also r: illegal ◁
      puts(_"Ambiguous prefix matches", stdout); print_prefix_name(p);
      puts(_"Ambiguous", stdout); print_prefix_name(r); err_print(">"); return name_dir;
      ▷ the unsection ◁
    }
    r ← p; ▷ remember match ◁
    p ← p-link; ▷ try another ◁
    q ← r-link; ▷ we’ll get back here if the new p doesn’t match ◁
    if (p ≡ Λ) p ← q, q ← Λ; ▷ q held the other branch of r ◁
  }
This code is used in section 59.
Although error messages are given in anomalous cases, we do return the unique best match when a discrepancy is found, because users often change a title in one place while forgetting to change it elsewhere.

```c
switch (section_name_cmp(&first, name_len, r)) {  // compare all of r with new name
  case prefix:
    if (!ispref) {
      fputs("\n!\nNew name is a prefix of\n"), stdout); print_section_name(r); err_print(">");
    } else if (name_len < prefix_length(r)) set_prefix_length(r, name_len);
    /* fall through */
  case equal: break;
  case extension:
    if (!ispref || first < last) extend_section_name(r, first, last + 1, ispref);
    break;
  case bad_extension: fputs("\n!\nNew name extends\n"), stdout); print_section_name(r);
    err_print(">"); break;
  default:     // no match: illegal
    fputs("\n!\nSection name incompatible with\n"), stdout); print_prefix_name(r);
    fputs("\n\nwhich abbreviates\n"), stdout); print_section_name(r); err_print(">");
    return r;
```

This code is used in section 59.

The error locations can be indicated by using the global variables `loc`, `cur_line`, `cur_file_name` and `changing`, which tell respectively the first unlooked-at position in `buffer`, the current line number, the current file, and whether the current line is from `change_file` or `cur_file`. This routine should be modified on systems whose standard text editor has special line-numbering conventions.

```c
int char *k, *l;  // pointers into buffer

if (changing && include_depth == change_depth)
  printf("\n!\n(\n!\n\%d of \nchange\nfile)\n", change_line);
else if (include_depth == 0) printf("\n!\n(\n!\n\%d)\n", cur_line);
else printf("\n!\n(\n!\n\%d of \ninclude\nfile)\n", cur_line, cur_file_name);

l ← (loc ≥ limit ? limit : loc);

if (l > buffer) {
  for (k ← buffer; k < l; k++)
    if (*k == '\n') putchar('\n');
    else putchar(*k);  // print the characters already read
    new_line;

  for (k ← buffer; k < l; k++) putchar('\n');  // space out the next line
}

for (k ← l; k < limit; k++) putchar(*k);  // print the part not yet read

if (*limit == '1') putchar('1');  // end of C text in section names

putchar('\n');  // to separate the message from future asterisks
```

This code is used in section 66.
When no recovery from some error has been provided, we have to wrap up and quit as graciously as possible. This is done by calling the function `wrap_up` at the end of the code.

CTANGLE and CWEAVE have their own notions about how to print the job statistics. See the function(s) `print_stats` in the interface above and in the index.

On multi-tasking systems like the AMIGA it is very convenient to know a little bit more about the reasons why a program failed. The four levels of return indicated by the `history` value are very suitable for this purpose. Here, for instance, we pass the operating system a status of 0 if and only if the run was a complete success. Any warning or error message will result in a higher return value, so that AREXX scripts can be made sensitive to these conditions.

```c
#ifndef RETURN_OK    /* No problems, success */
#define RETURN_OK   0

#ifndef RETURN_WARN   /* A warning only */
#define RETURN_WARN  5

#ifndef RETURN_ERROR  /* Something wrong */
#define RETURN_ERROR 10

#ifndef RETURN_FAIL   /* Complete or severe failure */
#define RETURN_FAIL  20
#endif
#endif
#endif
```

```c
int wrap_up(void)
{
    if (show_progress) new_line;
    if (show_stats) print_stats();  /* print statistics about memory usage */
#ifdef PRINT_JHISTORY
    (Print the job history 69*)
    switch (history) {
      case spotless: return RETURN_OK;
      case harmless_message: return RETURN_WARN;
      case error_message: return RETURN_ERROR;
      case fatal_message: default: return RETURN_FAIL;
    }
#endif
}
```

An overflow stop occurs if CWEB’s tables aren’t large enough.

```c
#include <stdio.h>

void overflow(const char *t)
{
    printf("\n!Sorry, capacity exceeded", t); fatal("", "");
}
```
Command line arguments. The user calls CWEAVE and CTANGLE with arguments on the command line. These are either file names or flags to be turned off (beginning with "-" ) or flags to be turned on (beginning with "+"). \TeX Live’s CWEB executables accept several "long options" as well; see section \langle Handle flag argument 80\rangle for details. The following globals are for communicating the user’s desires to the rest of the program. The various file name variables contain strings with the names of those files. Most of the 128 flags are undefined but available for future extensions.

\begin{verbatim}
\langle Global variables 18\rangle ≡
    int argc;    \triangleright copy of ac parameter to main
    char **argv; \triangleright copy of av parameter to main
    char C_file_name[max_file_name_length]; \triangleright name of C_file
    char tex_file_name[max_file_name_length]; \triangleright name of tex_file
    char idx_file_name[max_file_name_length]; \triangleright name of idx_file
    char scn_file_name[max_file_name_length]; \triangleright name of scn_file
    char check_file_name[max_file_name_length]; \triangleright name of check_file
    boolean flags[128]; \triangleright an option for each 7-bit code
\end{verbatim}

The flags will be initially false. Some of them are set to true before scanning the arguments; if additional flags are true by default they should be set before calling common_init.

\begin{verbatim}
\langle Set the default options common to CTANGLE and CWEAVE 74\rangle ≡
    make_xrefs ← true;
\end{verbatim}

This code is used in section 20*.  

\begin{verbatim}
73* Common code for CTANGLE and CWEAVE (4.9 [\TeX Live]) COMMAND LINE ARGUMENTS 17
\end{verbatim}
We now must look at the command line arguments and set the file names accordingly. At least one file name must be present: the CWEB file. It may have an extension, or it may omit the extension to get ".w" added. The \TeX\ output file name is formed by replacing the CWEB file name extension by ".tex", and the C file name by replacing the extension by ".c", after removing the directory name (if any).

If there is a second file name present among the arguments, it is the change file, again either with an extension or without one to get ".ch". An omitted change file argument means that "/dev/null" or—on non-UNIX systems the contents of the compile-time variable \texttt{DEV\_NULL} (\TeX\ Live) or \_\texttt{DEV\_NULL} (Amiga)—should be used, when no changes are desired.

If there's a third file name, it will be the output file.

```c
static void scan_args(void)
{
    char *dot_pos;    /* position of \textquote{.} in the argument */
    char *name_pos;   /* file name beginning, sans directory */
    char *s;         /* pointer for scanning strings */
    boolean found_web ← false, found_change ← false, found_out ← false;
        /* have these names been seen? */
    strcpy(change_file_name, "/dev/null");
    #if defined DEV\_NULL
        strcpy(change_file_name, DEV\_NULL, max_file_name_length − 2);
        change_file_name[max_file_name_length − 2] ← '\0';
    #endif
    #elif defined _DEV\_NULL
        strcpy(change_file_name, _DEV\_NULL, max_file_name_length − 2);
        change_file_name[max_file_name_length − 2] ← '\0';
    #endif
    while (−− argc > 0) {
        if ((**(++ argv) ≡ '\-' ∨ **argv ≡ '\+' ∨ (*argv + 1)) (Handle flag argument 80*)
            else {
                s ← name_pos ← *argv; dot_pos ← Λ;
                while (*s)
                    if (*s ≡ '\.') dot_pos ← s++;
                    else if (*s ≡ DIR\_SEPARATOR ∨ *s ≡ DEVICE\_SEPARATOR ∨ *s ≡ '/')
                        dot_pos ← Λ, name_pos ← ++s;
                    else s++;
            if (!found_web) (Make \texttt{web\_file\_name}, \texttt{tex\_file\_name}, and \texttt{C\_file\_name} 77*)
                else if (!found_change) (Make \texttt{change\_file\_name} 78)
                else if (!found_out) (Override \texttt{tex\_file\_name} and \texttt{C\_file\_name} 79)
                else (Print usage error message and quit 81*)
        }
        if (!found_web) (Print usage error message and quit 81*)
    }
```
We use all of `*argv` for the `web.file.name` if there is a `'.'` in it, otherwise we add ".w". The other file names come from adding other things after the dot. We must check that there is enough room in `web.file.name` and the other arrays for the argument.

```c
(Make web.file.name, tex.file.name, and C.file.name 77*)
{
    if (s − *argv > max.file.name_length − 5) (Complain about argument length 82*)
    if (dot_pos ∋ ∆) sprintf(web.file.name,"%s.w",*argv);
    else {
        strcpy(web.file.name,*argv); *dot_pos ← \’0\’;  ▷ string now ends where the dot was <
    }
    sprintf(tex.file.name,"%s.tex",name_pos); ▷ strip off directory name <
    sprintf(idx.file.name,"%s.idx",name_pos); sprintf(scn.file.name,"%s.scn",name_pos);
    sprintf(C.file.name,"%s.c",name_pos); found_web ← true;
}
This code is used in section 75*.

#define flag_change (**argv ≠ ‘-’)
(Handle flag argument 80*)
{
    if (strcmp("--help",*argv) ∋ 0 ∨ strcmp("−−help",*argv) ∋ 0) (Display help message and exit 97*)
    if (strcmp("--version",*argv) ∋ 0 ∨ strcmp("−−version",*argv) ∋ 0) (Display version information and exit 100*)
    if (strcmp("--verbose",*argv) ∋ 0 ∨ strcmp("−−verbose",*argv) ∋ 0) strcpy(*argv,"−v");
    if (strcmp("--quiet",*argv) ∋ 0 ∨ strcmp("−−quiet",*argv) ∋ 0) strcpy(*argv,"−q");
    for (dot_pos ← *argv + 1; *dot_pos > \’0\’; dot_pos++) {
        switch (*dot_pos) {

83* Output. Here is the code that opens the output file:

```c
(GLOBAL VARIABLES){18*} +≡
FILE *C_file; ▷ where output of CTANGLE goes ◄
FILE *tex_file; ▷ where output of CWEAVE goes ◄
FILE *idx_file; ▷ where index from CWEAVE goes ◄
FILE *scn_file; ▷ where list of sections from CWEAVE goes ◄
FILE *check_file; ▷ temporary output file ◄
FILE *active_file; ▷ currently active file for CWEAVE output ◄
char *found_filename; ▷ filename found by kpse_find_file ◄

84* (Scan arguments and open output files){84*} ≡
scan_args();
if (program ≡ ctangle) {
  if (check_for_change) (Open intermediate C output file){88*}
  else if ((C_file ← fopen(C_file_name, "wb")) ≡ Λ)
    fatal(⟨"!Cannot open output file") , C_file_name);
} else {
  if (check_for_change) (Open intermediate TpX output file){89*}
  else if ((tex_file ← fopen(tex_file_name, "wb")) ≡ Λ)
    fatal(⟨"!Cannot open output file") , tex_file_name);
}
```

This code is used in section 20*. 
Extensions to CWEB. The following sections introduce new or improved features that have been created by numerous contributors over the course of a quarter century.

Care has been taken to keep the original section numbering intact, so this new material should nicely integrate with the original “85. Index.”
86* Language setting. This global variable is set by the argument of the ‘+1’ (or ‘-1’) command-line option.

\begin{verbatim}
const char *use_language ← ""; ▷ prefix of cwebmac.tex in \TeX output ◄
\end{verbatim}
User communication. The scan_args and cb_show_banner routines and the bindtextdomain argument string need a few extra variables.

```c
#define max_banner 50
#define PATH_SEPARATOR separators[0]
#define DIR_SEPARATOR separators[1]
#define DEVICE_SEPARATOR separators[2]

char cb_banner[max_banner];
string texmf_locale;
 ifndef SEPARATORS
#define SEPARATORS "://"
 endif
 char separators[] ← SEPARATORS;
```
88* Temporary file output. Most C projects are controlled by a Makefile that automatically takes care of the temporal dependencies between the different source modules. It may be convenient that CWEB doesn’t create new output for all existing files, when there are only changes to some of them. Thus the make process will only recompile those modules where necessary. You can activate this feature with the ‘+c’ command-line option. The idea and basic implementation of this mechanism can be found in the program NUWEB by Preston Briggs, to whom credit is due.

⟨Open intermediate C output file 88*⟩≡

```
\{ if (((C_file ← fopen(C_file_name,"a")) ≡ Λ) fatal(\("!\underline{C}annot\underline{open}\underline{output}\underline{file}\underline{.}\underline{c}\"), C_file_name); else fclose(C_file); \> Test accessibility \<
strcpy(check_file_name, C_file_name);

  else strcpy(dot_pos,".ttp");
}
if (((C_file ← fopen(check_file_name,"wb")) ≡ Λ)
fatal(\("!\underline{C}annot\underline{open}\underline{output}\underline{file}\underline{.}\underline{c}\"), check_file_name);
```

This code is used in section 84*.

89* (Open intermediate \TeX output file 89*) ≡

```
\{ if (((tex_file ← fopen(tex_file_name,"a")) ≡ Λ)
fatal(\("!\underline{C}annot\underline{open}\underline{output}\underline{file}\underline{.}\underline{t}\underline{e}\underline{x}\"), tex_file_name);
else fclose(tex_file); \> Test accessibility \<
strcpy(check_file_name, tex_file_name);
if (check_file_name[0] \̸= '\0') {
  char *dot_pos ← strrchr(check_file_name, '.');
  if (dot_pos ≡ Λ) strcat(check_file_name,".wtp");
  else strcpy(dot_pos,".wtp");
}
if (((tex_file ← fopen(check_file_name,"wb")) ≡ Λ)
fatal(\("!\underline{C}annot\underline{open}\underline{output}\underline{file}\underline{.}\underline{t}\underline{e}\underline{x}\"), check_file_name);
```

This code is used in section 84*.

90* Before we leave the program we have to make sure that the output files are correctly written.

⟨Remove the temporary file if not already done 90*⟩≡

```
if (C_file) fclose(C_file);
if (tex_file) fclose(tex_file);
if (check_file) fclose(check_file);
if (strlen(check_file_name)) \> Delete the temporary file in case of a break \<
remove(check_file_name);
```

This code is used in section 68*. 

\}
Internationalization. If translation catalogs for your personal LANGUAGE are installed at the appropriate place, CTANGLE and CWEAVE will talk to you in your favorite language. Catalog cweb contains all strings from “plain CWEB,” catalog cweb-tl contains a few extra strings specific to the TeX Live interface, and catalog web2c-help contains the “--help” texts for CTANGLE and CWEAVE.

If such translation files are not available, you may want to improve this system by checking out the sources and translating the strings in files cweb.pot, cweb-tl.pot, and web2c-help.pot, and submitting the resulting *.po files to the maintainers at tex-k@tug.org.

Note to maintainers: CWEB in TeX Live generally does not set HAVE_GETTEXT at build-time, so i18n is “off” by default. If you want to create CWEB executables with NLS support, you have to recompile the TeX Live sources with a positive value for HAVE_GETTEXT in comm-w2c.h. Also you have to “compile” the NLS catalogs provided for CWEB in the source tree with msgfmt and store the resulting .mo files at an appropriate place in the file system.

Plans for TeX Live are to store NLS catalogs inside the “TeX Directory Structure” (TDS) and look them up with the help of the configuration variable “TEXMFLOCALEDIR,” which should contain a single absolute path definition. Below we use the KPATHSEA function kpse_var_expand to evaluate this variable from various origins and redirect the “GNU gettext utilities” to a possibly different location than the canonical /usr/share/locale.

There are several ways to set TEXMFLOCALEDIR:

(a) a user-set environment variable TEXMFLOCALEDIR
   (overridden by TEXMFLOCALEDIR_cweb);
(b) a line in KPATHSEA configuration file texmf.cnf,
   e.g., TEXMFLOCALEDIR=$TEXMFMAIN/locale
   or TEXMFLOCALEDIR.cweb=$TEXMFMAIN/locale.

⟨Include files 3*⟩ +≡
#if HAVE_GETTEXT
#include <locale.h>   ▷ LC_MESSAGES, LC_CTYPE ◁
#else
#define setlocale(a, b) ""
#define bindtextdomain(a, b) ""
#define textdomain(a) ""
#endif

92* (Set locale and bind language catalogs 92*) ≡
setlocale(LC_MESSAGES, setlocale(LC_CTYPE, ")

texmf_locale ← kpse_var_expand("${TEXMFLOCALEDIR}");
bindtextdomain("cweb", bindtextdomain("cweb-tl", bindtextdomain("web2c-help",
   strcmp(texmf_locale, ")" ? texmf_locale : "/usr/share/locale")));
free(texmf_locale);
textdomain("cweb");   ▷ the majority of "strings" come from “plain CWEB” ◁

This code is used in section 20*.
File lookup with KPATHSEA. The CTANGLE and CWEAVE programs from the original CWEB package use the compile-time default directory or the value of the environment variable CWEBINPUTS as an alternative place to be searched for files, if they could not be found in the current directory.

This version uses the KPATHSEA mechanism for searching files. The directories to be searched for come from three sources:

(a) a user-set environment variable CWEBINPUTS (overridden by CWEBINPUTS_cweb);
(b) a line in KPATHSEA configuration file texmf.cnf,
   e.g., CWEBINPUTS=$TEXMFDOTDIR:$TEXMF/texmf/cweb//
   or CWEBINPUTS.cweb=$TEXMFDOTDIR:$TEXMF/texmf/cweb//;
(c) compile-time default directories (specified in texmf.in),
   i.e., $TEXMFDOTDIR:$TEXMF/texmf/cweb//.

#include <kpathsea/kpathsea.h>
   // include every KPATHSEA header; kpathsea_debug, const_string, string
#include <w2c/config.h>   // integer
#include <lib/lib.h>     // versionstring

We set kpse_program_name to ‘cweb’. This means if the variable CWEBINPUTS.cweb is present in texmf.cnf (or CWEBINPUTS_cweb in the environment) its value will be used as the search path for filenames. This allows different flavors of CWEB to have different search paths.

#include <kpathsea/kpathsea.h>   // set up PROGNAME feature and initialize the search path mechanism
kpse_set_program_name(argv[0], "cweb");

This code is used in section 20*.

When the files you expect are not found, the thing to do is to enable KPATHSEA runtime debugging by assigning to the kpathsea_debug variable a small number via the ‘-d’ option. The meaning of this number is shown below. To set more than one debugging option, simply sum the corresponding numbers.

1 report ‘stat’ calls
2 report lookups in all hash tables
4 report file openings and closings
8 report path information
16 report directory list
32 report on each file search
64 report values of variables being looked up

Debugging output is always written to stderr, and begins with the string ‘kdebug:’. 
Common code for CTANGLE and CWEAVE (4.9 [\TeX Live])

System Dependent Changes

The most volatile stuff comes at the very end.

Modules for dealing with help messages and version info.

\begin{verbatim}
#include "help.h"
\end{verbatim}

Display help message and exit

\begin{verbatim}
static void cb_usage(const_string str);
static void cb_usagehelp(const_string *message);
\end{verbatim}

Display version information and exit

\begin{verbatim}
void cb_show_banner(void)
{  
  textdomain("cweb-1l");  printf("%s\n", versionstring);  textdomain("cweb");
}
\end{verbatim}

The version information will not be translated, it uses a generic text template in English.

\begin{verbatim}
printversionandexit(cb_banner,
    program \equiv ctwill ? "Donald\textquotesingle{}E.\textquotesingle{}Knuth": "Silvio\textquotesingle{}Levy\textquotesingle{}and Donald\textquotesingle{}E.\textquotesingle{}Knuth", 
                         "Contemporary development on \url{https://github.com/ascherer/cweb}.
                         textdomain("cweb");
    history \leftarrow spotless;  exit(wrap_up());
}
\end{verbatim}

But the “banner” is, at least the first part.

\begin{verbatim}
int check_version(void)
{  
  textdomain("cweb-1l");  printf("%s\n", cb_banner, versionstring);  textdomain("cweb");
}  
\end{verbatim}
