

A Document Class and a Package for handling multi-files projects

Federico Garcia
(v1.2 update by Gernot Salzer)

2018/07/31

Abstract

With the `subfiles` set, the typesetting of a multi-file project consisting of one main file and one or more subsidiary files (subfiles) is more comfortable, since the user can \LaTeX either the main file, which will `\input` the subfiles normally, or the subfiles by themselves, which take the preamble of the main file and become self-sufficient \LaTeX documents.

1 Introduction

\LaTeX commands `\include` and `\input` allow for the creation of different input files to be typeset jointly into a single output. The advantages of this are evident in the creation of large documents with many chapters, but there are also other circumstances in which the author might want to use this feature. I have used it particularly for long-coded examples, tables, figures, etc.¹, which require a considerable amount of trial-and-error.

In this process the rest of the document is of little use, and it can even disturb.² Frequently, one ends up wanting to work *only* on the new file, which means following three steps:

- Create a new file, and copy-paste in it the preamble of the main file;
- Work in the example, typeset it *alone* as many times as necessary;
- When the result is satisfactory, delete the preamble from the new file (and the `\end{document}!`), and `\include` or (more frequently) `\input` it from the main file.

It is desirable to reduce these three steps to the only interesting one, the middle one. This would mean that each new, subordinated file (henceforth, ‘subfile’)

¹In my case most times it has been musical examples, whose code in MusiX \TeX is long, intricate, and barely readable.

²For example, the error messages indicate not only a wrong line number, but even the wrong file.

should be *both* part of a project and a self-sufficient L^AT_EX document, depending on whether it is L^AT_EXed or `\included/\input`. This is what the set of class and package under the name `subfiles` is intended for.

The main idea behind it is the redefinition of `\documentclass` and the `document` environment; while these two features of L^AT_EX are important to keep unchanged, `subfiles` changes them, as far as I know, harmlessly, and I have taken care of undoing the changes when finished. This is the first version of `subfiles`, and although I have tried it a few times, it is still susceptible to conflicts with other packages and/or classes. (In fact, a conflict with the `revtex4` class later gave rise to version 1.2 of the package.)

2 Usage

2.1 Setting up

The files involved have the following basic structures:

<i>MAIN FILE</i>	<i>SUBFILE</i>
<i><some preamble></i>	<code>\documentclass[<i><main_file_name></i>]{subfiles}</code>
<code>\usepackage{subfiles}</code>	<code>\begin{document}</code>
<code>\begin{document}</code>	<i><text, graphics, etc.></i>
<i><text></i>	<code>\end{document}</code>
<code>\subfile{<i><subfile_name></i>}</code>	
<i><more text></i>	
<code>\end{document}</code>	

The `subfiles` package is to be loaded in the main file of a L^AT_EX project at the end of the preamble, and the `subfiles` class is to be loaded by each subordinate file. Note that the `subfiles` class handles only *one* ‘option’ (whose presence is actually mandatory), the name of the main file. The name should be given according to T_EX conventions: `.tex` is the default extension; the path has to be indicated (`/`, not `\`) if the main file is in a different directory from the subfile; spaces are gobbled (at least under Windows).

2.2 Results

This done, L^AT_EXing either the main or the subordinate file produces the following results:

- If the subfile is typeset by itself, it takes as preamble the one of the main file (including its `\documentclass`). The rest is typeset normally.
- If the subordinated file was `\subfile`'d, it ignores everything before and including `\begin{document}`, and then ignores `\end{document}` too. (The body of the file, nothing else, is effectively `\input`.)

The `\subfile` command is more like `\input` than `\include` in the sense that it does not start a new page. It allows nesting, but there is no exclusion mechanism analogous to `\includeonly`.

2.3 Further details and warnings

To be precise, a subfile typeset by itself does not exactly take the preamble of the main file, but *everything outside* `\begin{document}` and `\end{document}`. This has two consequences: *a*) the user can add some commands to be read only when the subfiles are typeset by themselves—which in any case are processed as part of the preamble; but also *b*) the user has to be careful even *after* `\end{document}` (in the main file), for any syntax error there will ruin the \LaTeX ing of the subfile(s).

The preamble of the main file can `\input` (not `\include` nor `\subfile`) other files (e.g. files with definitions and shorthand-commands), and the subfiles will too. But it has to be kept in mind that each subfile is `\input` within a group, so definitions made within them might not work outside. A good practice when using `subfiles` (and also when not using it) is to make any definitions in the preamble of the main file, avoiding confusion and allowing to find them easily.

In principle, nesting files with `\subfile` should work and has worked in my tries, as far as every subfile loads the main file as its option to the `subfiles` class. However, who knows, the behavior can be unpredictable in weird situations. In any case, `subfiles` does *not* disable `\include` nor `\input`, which remain available for free use.

The `subfiles` package requires the `verbatim` package (whose `comment` environment is used to ignore the different parts of different files); this should not be a problem since it makes part of the standard distribution of $\text{\LaTeX}2_{\epsilon}$.

2.4 Version history

v1.1: Start of version history. Written by Federico Garcia.

v1.2: The `subfiles` package is now compatible with classes and packages that modify the `\document` command, like the class `revtex4`. Modification by Gernot Salzer.

3 The Implementation

3.1 The class

```
1 <{*class}>
2 \NeedsTeXFormat{LaTeX2e}
3 \ProvidesClass{subfiles}[2018/07/31 Federico Garcia, Gernot Salzer]
4 \DeclareOption*{\typeout{Preamble taken from file '\CurrentOption'}}%
5   \let\preamble@file\CurrentOption}
6 \ProcessOptions
```

The first thing to do is to save the regular \LaTeX definition of `\documentclass`:

```
7 \let\old@documentclass@subfiles\documentclass
```

Now `\documentclass`, after having already loaded `subfiles.cls`, is set equal to `\LoadClass` such that the class and the options of the main file will be loaded identically.

```
8 \let\documentclass\LoadClass\relax
```

Now it is possible to `\input` the main file. The main file loads the package `subfiles` as part of the preamble, which saves the contents of `\document` and `\enddocument` as `\old@document@subfiles` and `\old@enddocument@subfiles`, respectively. After having loaded the main file, we can restore the original values of `\document`, `\enddocument` and `\documentclass`. The backup commands are `\undefined` to save memory. That's it.

```
9 \input{\preamble@file}
10 {\catcode'\@=11
11 \global\let\document\old@document@subfiles
12 \global\let\enddocument\old@enddocument@subfiles
13 \global\let\documentclass\old@documentclass@subfiles
14 \global\let\old@document@subfiles\undefined
15 \global\let\old@enddocument@subfiles\undefined
16 \global\let\old@documentclass@subfiles\undefined}
17 \endclass
```

It may not be obvious why `@` has to be catcoded to a letter, since we are in a style file anyway. However, the `\preamble@file` occasionally contains `\usepackage` commands that make `@` a non-letter. This is why the part after loading the main preamble needs a `\catcode` command, grouping, and `\global`'s.

3.2 The package

Any option will be ignored.

```
18 \*package)
19 \NeedsTeXFormat{LaTeX2e}
20 \ProvidesPackage{subfiles}[2018/07/31 Federico Garcia, Gernot Salzer]
21 \DeclareOption*{\PackageWarning{\CurrentOption ignored}}
22 \ProcessOptions
23 \RequirePackage{verbatim}
```

`\skip@preamble`

The core of the package. It works by redefining the `document` environment, thus making `\begin{document}` and `\end{document}` of the subfile transparent to the inclusion. The redefinition of `\documentclass` is analogous, just having a required and an optional arguments which mean nothing to `\subfile`.

```
24 \newcommand{\skip@preamble}{%
25   \let\document\relax\let\enddocument\relax%
26   \newenvironment{document}{}{}%
27   \renewcommand{\documentclass}[2][subfiles]{}}
```

`\subfile`

Note that the new command `\subfile` calls for `\skip@preamble` *within a group*. The changes to `document` and `\documentclass` are undone after the inclusion of the subfile.

```
28 \newcommand\subfile[1]{\begingroup\skip@preamble\input{#1}\endgroup}
```

If the package is being processed as part of the main file, then we are done. However, if the initial document class was `subfiles`, then the main file is loaded as part of a subfile. In this case the subsequent text between `\begin{document}` and `\end{document}` has to be skipped, but the contents of the commands `\document` and `\enddocument` has to be retained for using it with the contents of the subfile.

Therefore we save the contents of the two commands as `\old@document@subfiles` and `\old@enddocument@subfiles`, respectively. Now the `document` environment is redefined to become the `comment` environment from the `verbatim` package. As a consequence, the body of the main file is ignored by L^AT_EX, and only the preamble is read (and anything that comes after `\end{document}`!).

```
29 \@ifclassloaded{subfiles}{%
30   \let\old@document@subfiles\document
31   \let\old@enddocument@subfiles\enddocument
32   \let\document\comment
33   \let\enddocument\endcomment
34 }{}
35 \</package>
```

By loading the `subfiles` package immediately before `\begin{document}` we ensure that `\old@document@subfiles` and `\old@enddocument@subfiles` contain all modifications that the class and the preamble of the main file may have applied to the `document` environment. E.g., the class `revtex4` prepends some commands to `\document`.
